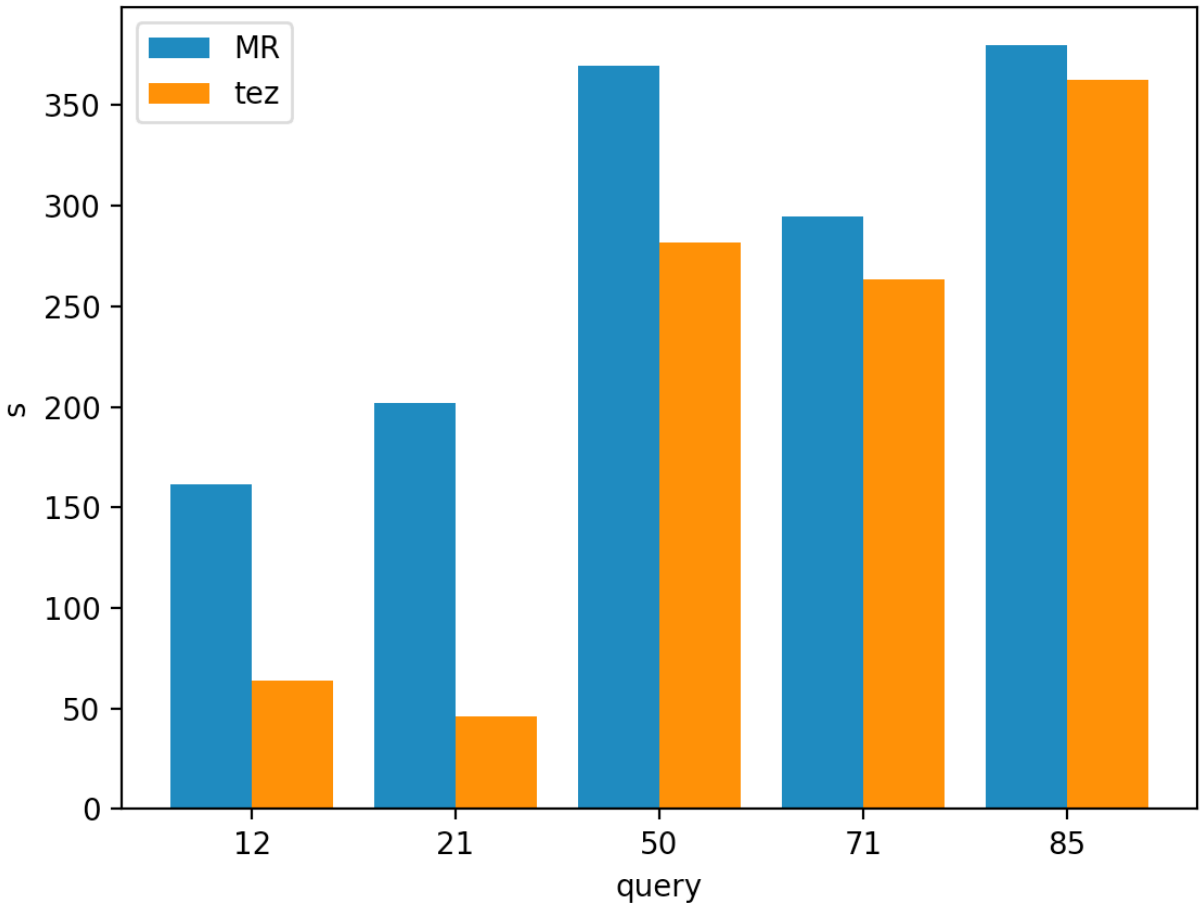
Part A.

Question 1

a

Yes,The observation is that Hive/Tez is always better than Hive/MR. However, how much it is better varies from query to query. It is not a constant because the job assignment and structure differs from query to query.



b

Please see the plots for total amount of data for each query and the bandwidth for each query below.
Bandwidth: since we can only calculate throughput instead of bandwidth, which is the upper bound of the throughput. The throughput is shown below and it is a approximation of bandwidth.
Observation: TEZ has more writing to the disks. Explanation: Tez uses different strategies of reduce from MR.
Trend: Generally speaking, Tez has a higher disk reading throughput. It can be verified by the DAG of the jobs, Tez has more jobs reading from the disk independently(simultaneously) and thus reach a higher reading throughput.

Throughput for disks: (MB)

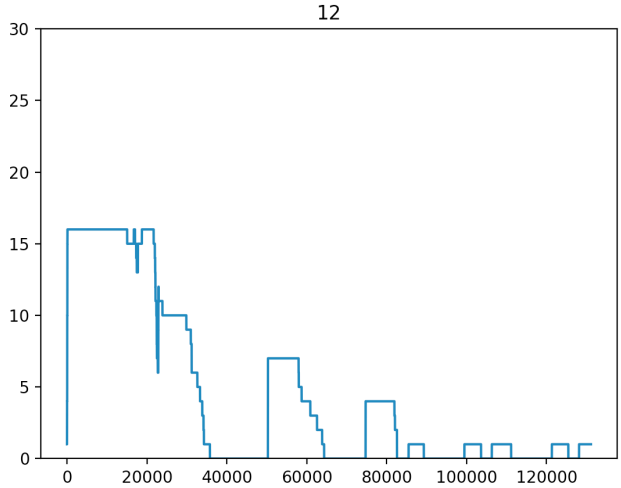
C

For map reduce:

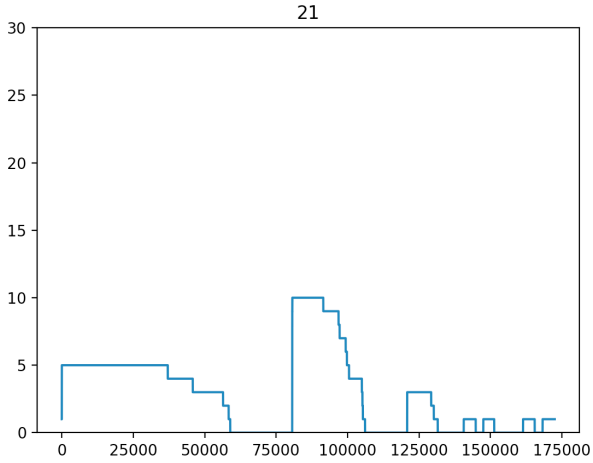
Query 12

total tasks: 42
number of map tasks: 39
number of reduce tasks: 3
ratio of reduce versus map: 0.07692307692307693



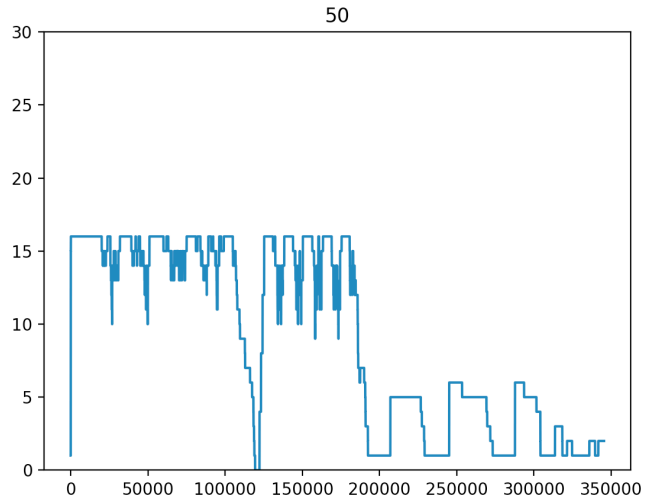
Query 21

total tasks: 22
number of map tasks: 20
number of reduce tasks: 2
ratio of reduce versus map: 0.1



Query 50

total tasks: 188
number of map tasks: 99
number of reduce tasks: 89
ratio of reduce versus map: 0.898989898989899



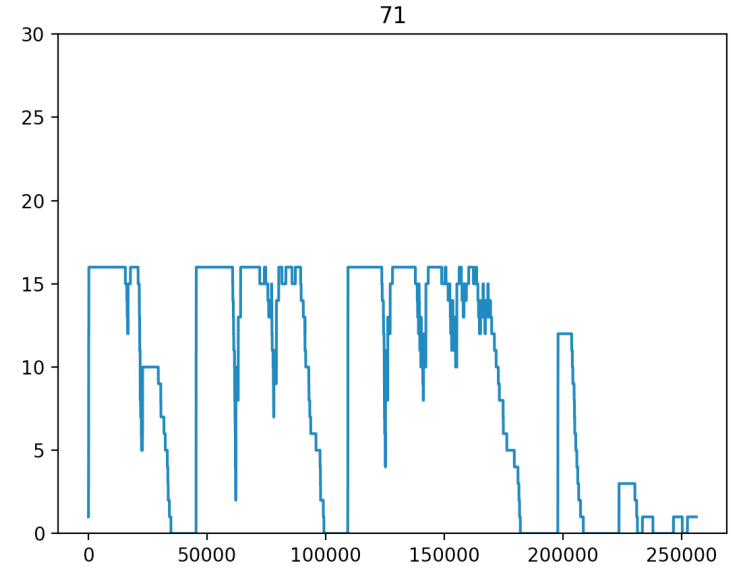
Query 71

total tasks: 170

number of map tasks: 168

number of reduce tasks: 2

ratio of reduce versus map: 0.011904761904761904



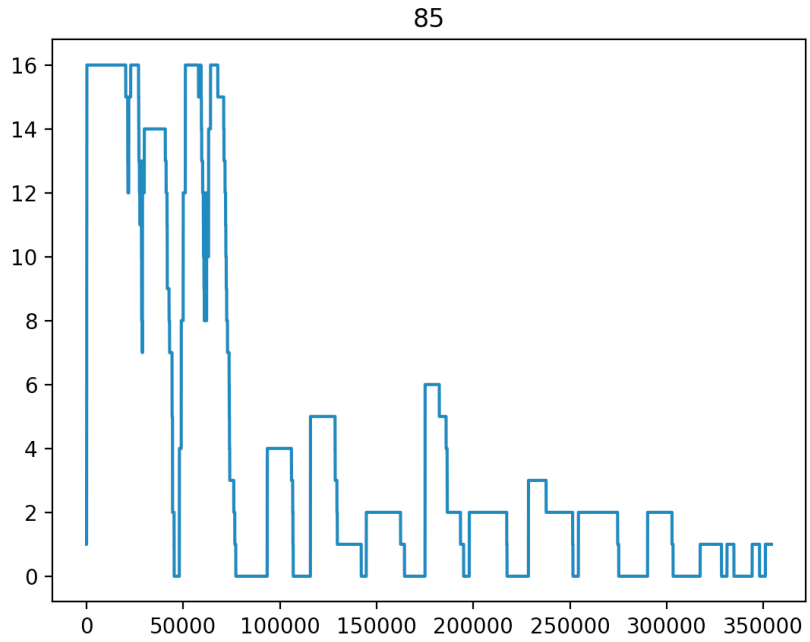
Query 85

total tasks: 92

number of map tasks: 52

number of reduce tasks: 40

ratio of reduce versus map: 0.7692307692307693



For Tez:

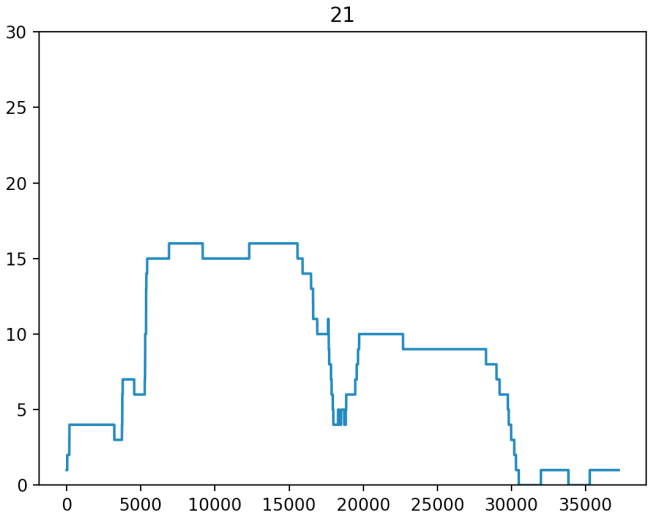
query 12

total tasks : 55

number of map tasks : 52

number of reduce tasks: 3

ratio of reduce versus map: 0.057692307692307696



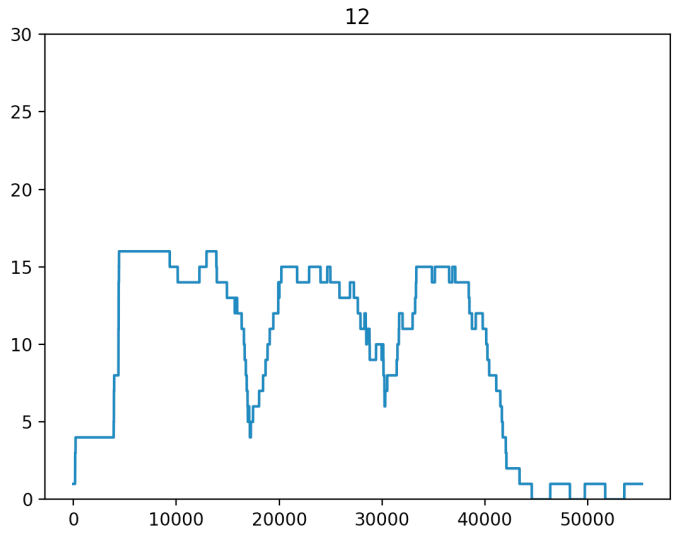
query 21

total tasks : 30

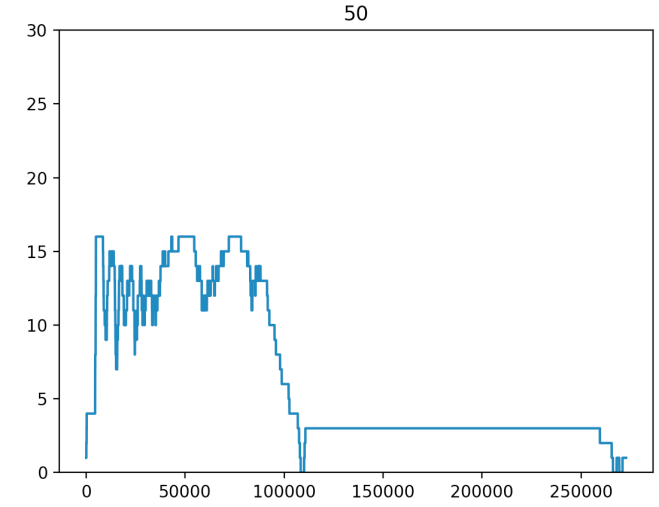
number of map tasks : 28

number of reduce tasks: 2

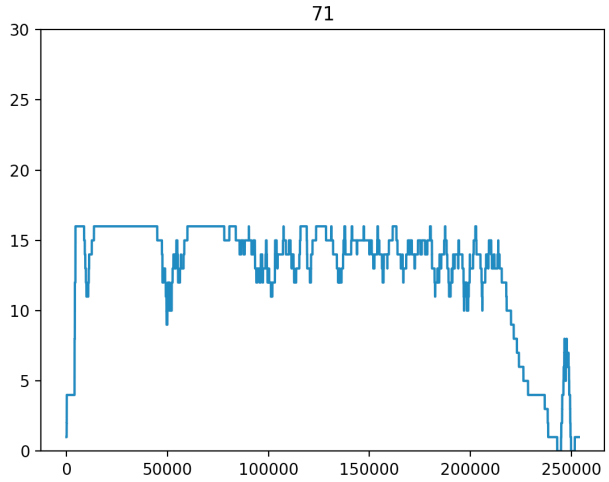
ratio of reduce versus map: 0.07142857142857142



query 50
total tasks : 97
number of map tasks : 92
number of reduce tasks: 5
ratio of reduce versus map: 0.05434782608695652



query 71
total tasks : 144
number of map tasks : 129
number of reduce tasks: 15
ratio of reduce versus map: 0.11627906976744186



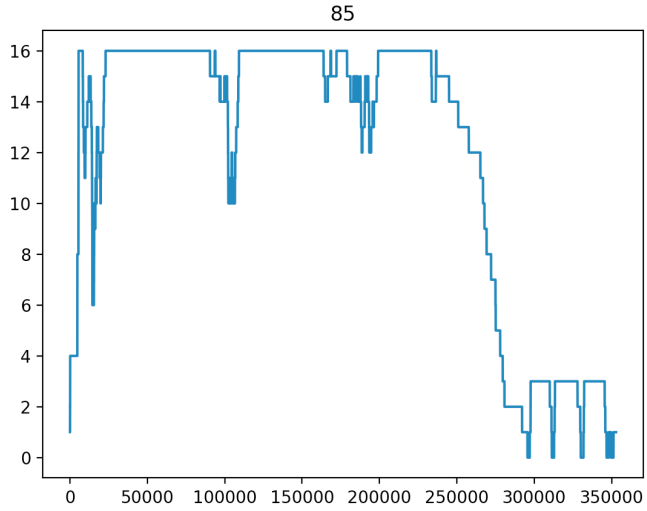
query 85

total tasks : 83

number of map tasks : 72

number of reduce tasks: 11

ratio of reduce versus map: 0.1527777777777778



Correlation:

The higher number of total tasks, the higher the overall throughput will be.

The higher number of map tasks, the higher the reading throughput will be, and same story happens to the number of reduce tasks and writing throughput.

d.

85:

These DAGs are very different.

Yes, the structure can impact the performance. Say we have many independent mapping tasks reading from HDFS simultaneously, then we have a higher reading from disk throughput. If we just have a sequential structure, we can only have a lower throughput because the nest stage depends of the result of the previous one. This can be verified by observing difference of reading throughput of Tez and MR in query 12, query 21 and query 50.

2.

Mapreduce:
Normal: 296.7 s
25%: 386.5 s
75%: 355.5 s

Tez:
Normal: 263.2s
25%: 325.9s
75%: 301.3s
We observed that In both MR and Tez, failing a slave can slow the query. The earlier the slave is failed, the slower it will be.
Firstly, failures happened and it takes time to recover from the failures and re-schedule the particular jobs.
Secondly, some of the jobs can be executed in a parallel way at the first place, however after the data node fails, they can no longer be executed in a parallel style because the only copy of the data on the failed node is in the busy node and it can only be executed after the current job is finished. It explains that the earlier it fails, the slower it will be: the earlier it fails, less jobs can be done in parallel.
